AB   The present invention relates to methods for identifying compds. that
     inhibit PTP1B (protein tyrosine phosphatase 1B) mRNA and protein
     expression in insulin resistant obese non-human mammals.
     The present invention relates to biol. markers for PTP1B inhibition or
     redn.  Specifically, the present invention relates to methods for
     measuring the downregulation of the p85.alpha. regulatory subunit of
     phosphatidylinositol-3-kinase and the upregulation of p55.alpha. and/or
     p50.alpha. isoforms in response to in vivo inhibition or redn. of PTP1B in
     insulin resistant mammals.  Moreover, the present invention relates to an
     in vivo marker for pharmacodynamic measurements and mechanism of action
     detns. of small mol. drugs which inhibit or reduce PTP1B activity.
     Finally, the present invention also provides a method to screen agents for
     activity that down modulates p85.alpha. and upregulates
     phosphatidylinositol-3-kinase p85.alpha. isoforms as drugs for the
     treatment of type 2 diabetes.

AB A method and kit for detecting endocrine-disrupting chems. using DNA microarrays are claimed. The method comprises prepg. a nucleic acid sample contg. mRNAs or cDNAs originating in cells, tissues, or organisms which have been brought into contact with a sample contg. the endocrine disruptor. The nucleic acid sample is hybridized with DNA microarrays having genes affected by the endocrine disruptor or DNA fragments originating in these genes have been fixed. The results obtained are then compared with the results obtained with the control sample to select the gene affected by the endocrine disruptor. Genes whose **expression** is altered by tri-Bu tin, 4-octaphenol, 4-nonylphenol, di-N-Bu phthalate, dichlorohexyl phthalate, octachlorostyrene, benzophenone, diethylhexyl phthalate, diethylstilbestrol (DES), and 17-.beta. estradiol (E2), were found in mice by DNA chip anal.

AB The previously isolated cDNA encoding **human adenylate kinase** (AK) isozyme 3 was recently renamed AK4. Consequently, **human** AK3 cDNA remains to be identified and we have little information about the functional relationship between **human** AK3 and AK4. In pursuit of the physiological roles of both the AK3 and AK4 proteins, we first isolated an authentic **human** AK3 cDNA and compared their **expression**. Nucleotide sequencing revealed that the cDNA encoded a 227-amino-acid protein, with a deduced molecular mass of 25.6 kDa, that shares greater homology with the AK3 cDNAs isolated from

bovine and rat than that from **human**. We named the isolated cDNA AK3. Northern-blot analysis revealed that AK3 mRNA was present in all tissues examined, and was highly **expressed** in heart, skeletal muscle and liver, moderately **expressed** in pancreas and kidney, and weakly **expressed** in placenta, brain and lung. On the other hand, we found that **human** AK4 mRNA was highly **expressed** in kidney, moderately **expressed** in heart and liver and weakly **expressed** in brain. Western-blot analysis demonstrated **expression** profiles of AK3 and AK4 that were similar to their mRNA **expression** patterns in each tissue. Over **expression** of AK3, but not AK4, in both Escherichia coli CV2, a temperature-sensitive AK mutant, and a **human** embryonic kidney-derived cell line, HEK-293, not only produced significant GTP:AMP phosphotransferase (AK3) activity, but also complemented the CV2 cells at 42 degrees C. Subcellular and submitochondrial fractionation analysis demonstrated that both AK3 and AK4 are localized in the **mitochondrial** matrix.

ABSTRACT IS AVAILABLE IN THE ALL AND IALL FORMATS

AB 2',3'-dideoxyadenosine 5-monophosphate (ddAMP), is a key intermediate in the metabolism of the antiviral agent 2',3'-dideoxyinosine (ddI) to its active triphosphate derivative, 2',3'-dideoxyadenosine-5'-triphosphate (ddATP). The potential role of **adenylate kinase** in the phosphorylation of ddAMP was studied in **human** peripheral blood mononuclear cells (PBMC) and a **human** T cell line, CEMss. Subcellular distribution, sulfhydryl inhibitor, and substrate specificity studies support the hypothesis that the **mitochondrial adenylate kinase** (AK2) is a major route of cellular activation of these compounds in **human** lymphocytes.

AB As a step toward understanding of the role of **adenylate kinase** (AK) in energy metabolism, we analyzed this enzyme in

Drosophila melanogaster. The enzyme activities of all three AK isozymes were determined in cell-free extracts of flies, and their proteins were detected by Western blot analysis using polyclonal antibodies against the mammalian isozymes. A cDNA encoding **adenylate kinase** was isolated from D. melanogaster cDNA library. The cDNA encodes a 240-amino acid protein, which shows high similarity to bovine, **human** and rat AK2, and hence was named DAK2. Preliminary subcellular fractionation analysis indicated that DAK2 is localized in both cytoplasm and **mitochondria**. In situ hybridization to salivary gland polytene chromosomes revealed that the Dak2 gene is located at 60B on the right arm of the second chromosome.

AB As a step toward understanding of the role of **adenylate kinase** (AK) in energy metabolism, we analyzed this enzyme in Drosophila melanogaster. The enzyme activities of all three AK isozymes were determined in cell-free extracts of flies, and their proteins were detected by Western blot analysis using polyclonal antibodies against the mammalian isozymes. A cDNA encoding **adenylate kinase** was isolated from D, melanogaster cDNA library. The cDNA encodes a 240-amino acid protein, which shows high similarity to bovine, **human** and rat AK2, and hence was named DAK2. Preliminary subcellular fractionation analysis indicated that DAK2 is localized in both cytoplasm and **mitochondria**. In situ hybridization to salivary gland polytene chromosomes revealed that the Dak2 gene is located at 60B on the right arm of the second chromosome. (C) 2000 Elsevier Science B.V. AB The authors **cloned** cDNAs encoding four **adenylate kinase** (AK) isoenzymes from a mouse kidney cDNA library. The AK1, AK2, AK3, and AK4 cDNAs encode the 194-, 232-, 227-, and 223-amino acid proteins, resp. AK4 is a recently isolated gene that is highly homologous to the reported **human** AK3. Northern blot anal. and reverse transcription-polymerase chain reaction anal. revealed that AK1 mRNA was predominantly **expressed** in skeletal muscle, heart, and testis; AK2 mRNA in liver, heart, kidney, and testis; AK3 mRNA almost uniformly in all tissues examd.; and AK4 mRNA prominently in kidney. Subcellular and submitochondrial fractionation anal. suggested that AK4 was localized in the **mitochondrial** matrix. Further, the authors found a 76-fold induction of AK1 mRNA **expression** concomitant with a 53-fold induction of NeuroD **expression** during retinoic acid-induced neuronal differentiation of P19 embryonic carcinoma cell. AK2 and AK3 mRNA **expression** was increased by 4- to 6-fold during differentiation, whereas AK4 transcription was first down-regulated and subsequently returned to the original level. These data on AK isoenzyme gene **expression** may provide basic information for prodn. and evaluation of transgenic mice as well as knockout mice to further understand the physiol. role of AK isoenzymes.

AB Activation of pro-caspase-3 is a central event in the execution phase of apoptosis and appears to serve as the convergence point of different apoptotic signaling pathways. Recently, **mitochondria** were found to play a central role in apoptosis through release of cytochrome c and activation of caspases. Moreover, a sub-population of pro-caspase-3 has been found to be localized to this organelle. In the present study, we demonstrate that pro-caspase-3 is present in the **mitochondrial** fraction of Jurkat T cells in a complex with the chaperone proteins Hsp60 and Hsp10. Induction of apoptosis with staurosporine led to the activation of **mitochondrial** pro-caspase-3 and its dissociation from the Hsps which were released from **mitochondria**. The release of Hsps occurred simultaneously with the release of other **mitochondrial** intermembrane space proteins including cytochrome c and **adenylate kinase**, prior to a loss of **mitochondrial** transmembrane potential. In in vitro systems, **recombinant** Hsp60 and Hsp10 accelerated the activation of pro-caspase-3 by cytochrome c and dATP in an ATP-dependent manner, consistent with their function as chaperones. This finding suggests that the release of **mitochondrial** Hsps may also accelerate caspase activation in the cytoplasm of intact cells.

AB A purified **mitochondrial adenylate-kinase** (EC-2.7.4.3) with a given protein sequence is claimed. Also claimed is a nucleic acid encoding the kinase, of given nucleotide sequence, and that hybridizes, under stringent conditions, with the given nucleic acid sequence. The claims also cover a nucleic acid complementary to the given sequence, and a DNA probe that constitutes part of that complementary sequence. Also covered are an **expression** vector containing the given nucleic acid sequence, a host cell transformed by that vector, and a means of preparing the **adenylate-kinase** by culturing the transformed cell, and recovering the protein. The claims extend to a composition containing the **adenylate-kinase**, and an antibody, agonist and antagonist of the protein. These are used to treat neurological disorders, cancer and immunological disorders. Also claimed is a means of detecting nucleic acids encoding **mitochondrial adenylate-kinase** in a sample using the DNA probe, and detecting the hybridization complex. The nucleic acids can also be administered for gene therapy. (63pp)

AB We identify a novel subtype of **adenylate kinase**, which is the 4th **adenylate kinase** (AK4), in the vertebrate. AK4 mRNA is **expressed** in the mammalian central nervous system in a region-specific manner from the middle stage of embryogenesis to the adulthood in the rodent. The presence of three isozymes of **adenylate kinase** (AK1, AK2 and AK3) that maintains the homeostasis of adenine and guanine nucleotide composition has been reported in the vertebrate. Obtained mouse AK4 cDNA is 3667 bp in size. The predicted open reading frame consists of 223 amino acid residues. Rat AK4 cDNA is also obtained, and the predicted open reading frame is the same length as that of the mouse. The predicted rat AK4 molecule shows 97.8% homology with mouse AK4. Rat AK4 protein is distinct from rat AK3, 53.8% homologous with rat AK3, although the **adenylate kinase** signature and the **mitochondrial** energy transfer protein signature are found in both sequences. Interestingly, rat AK4 is 89.2% homologous with the **human** AK3 over 223 amino acid residues and rat AK3 is 53.7% homologous with the **human** AK3 indicating that the reported **human** AK3 actually belongs to the AK4 group (therefore, it should be referred to as **human** AK4). Although the sequence of AK4 is most similar to that of AK3 among the AK isozymes, its in vivo **expression** is completely different from AK3; AK4 mRNA is **expressed** in the pyramidal cells in the hippocampus (mainly in the subfield CA3), the granular cells in the cerebellum, nasal neuroepithelium and the liver while AK3 mRNA is **expressed** ubiquitously in the body. It is probable that AK4 acts on the specific mechanism of energy metabolism rather than control of the homeostasis of the ADP pool ubiquitously.

SUMMARY LANGUAGE: English

AB **Human** p32, originally **cloned** as a splicing factor 2-associated protein, has been reported to interact with a variety of molecules including **human** immunodeficiency virus Tat and complement 1q (C1q). p32 protein is supposed to be in the nucleus and on the plasma membrane for the association with **human** immunodeficiency virus Tat and C1q, respectively. None of the interactions, however, is proven to have a physiological role. To investigate the physiological function of p32, we determined the intracellular localization of p32. The fractionation of cells, fluorescent immunocytochemistry, and electron microscopic immunostaining show that p32 is exclusively localized in the **mitochondrial** matrix. We **cloned** a Saccharomyces cerevisiae homologue of **human** p32 gene, referred to yeast p30 gene. The yeast p30 protein is also localized in the **mitochondrial** matrix. The disruption of the p30 gene caused the growth retardation of yeast cells in a glycerol medium but not in a glucose medium, i.e. the impairment of the **mitochondrial** ATP synthesis. The growth impairment was restored by the introduction of the **human** p32 cDNA, indicating that p30 is a functional yeast counterpart of **human** p32. Taken together, both p32 and p30 reside in **mitochondrial** matrix and play an important role in maintaining **mitochondrial** oxidative phosphorylation.

AB 14-3-3 proteins play a role in many cellular functions as molecular chaperone and adapter proteins: they bind to and modulate several proteins involved in cell proliferation and differentiation, and also function ATP-dependently in targeting of precursors to **mitochondria**. We show here that 14-3-3 purified from a **human** lymphoblastoma and also its **recombinant** tau isoform exhibited intrinsic nucleoside diphosphate (NDP) kinase-like activity. 14-3-3 proteins preferentially catalyzed the transfer of the gamma-phosphate group from ATP, dATP or dGTP to all nucleoside diphosphates and this transfer involved acid-labile phosphoenzyme intermediates. They also simultaneously catalyzed the reverse reaction of ATP hydrolysis. These properties of 14-3-3 are similar to those of NDP kinase, but not to those of **adenylate kinase**.

ABSTRACT IS AVAILABLE IN THE ALL AND IALL FORMATS

AB The current problems of regulation of myocardial energy metabolism and oxidative phosphorylation in vivo are considered, With this purpose, retarded diffusion of ADP in cardiomyocytes was studied by analysis of elevated apparent K-m for this substrate in regulation of respiration of saponin-skinned cardiac fibers, as compared to isolated **mitochondria**. Recently published data showing the importance of the outer **mitochondrial** membrane were compared with new experimental results on the proteolysis of skinned fibers and tissue homogenates. In both cases 10 min incubation and 0.125 mg/ml of trypsin resulted in a decrease of apparent K-m for ADP from 297 +/- 35 and 228 +/- 16 to 109 +/- 2 and 36 +/- 16, respectively. Thus, the permeability of the outer **mitochondrial** membrane for ADP may be controlled by some unknown cytoplasmic protein(s), probably related to the cytoskelton, which are separated from **mitochondria** during their isolation. The extent of **expression** of this protein(s) depends on the energy state and type of muscle. Activation of **mitochondrial** creatine kinase reaction coupled to oxidative phosphorylation overcomes the diffusion difficulties of ADP by amplifying the stimulatory effect of ADP on respiration. It is concluded that both cytoplasmic and **mitochondrial** creatine kinases, **adenylate kinase** and cytoplasmic factor controlling outer membrane permeability may participate in metabolic feedback regulation of respiration in muscle cells.

AB **Human** fibroblasts in culture have never been found to transform spontaneously into immortal cells. In an effort to generate an infinite life span cell strain from foreskin-derived normal diploid fibroblasts, we transfected the cells with a plasmid carrying a v-myc oncogene linked to the neo gene, or with a control vector carrying the neo gene, and selected drug-resistant **clones**. A **clone** that **expressed** the v-myc protein was propagated to the end of its life span, with periodic cryogenic storage of the progeny. The population went into crisis at the same time as cells from the control population and eventually senesced. However, while the cells were senescing, viable-appearing **clones** were noted. The cells of these **clones** continued to multiply, very slowly at first but eventually at a faster rate. Analysis showed that these cells have a diploid karyotype that has remained stable throughout more than 200 population doublings since their sibling cells senesced. Molecular analysis showed that the infinite life span cells are, indeed, derived from the cells used for transfection, and that they continue to **express** the v-myc protein.

AB Pyruvate carboxylase (PC) (pyruvate:carbon dioxide ligase (ADP-forming), EC 6.4.1.1.), a nuclear-encoded **mitochondrial** enzyme, catalyzes the conversion of pyruvate to oxaloacetate. We have isolated and characterized cDNAs spanning the entire coding region of **human** PC. The sequence of **human** PC has an open reading frame of 3537 nucleotides which encodes for a polypeptide with a length of 1178 amino acids. The identity of the cDNA as PC is confirmed by comparison to PC cDNAs of other species and sequenced peptide fragments of mammalian PC. The M(r) of the full length precursor protein is 129 576 and that of the mature apoprotein is 127 370. RNA blot analysis from a variety of **human** tissues demonstrates that the highest level of PC mRNA is found in liver corresponding to this tissue's high level of PC activity. Based on homology with other biotin-containing proteins, the ATP, pyruvate, and biotin-binding sites can be identified. One of two patients with documented PC deficiency was found to be missing PC mRNA, further confirming the identity of this cDNA.

ABSTRACT IS AVAILABLE IN THE ALL AND IALL FORMATS

AB Thymidine kinases were described for cellular life long before it was shown that they could also be encoded by viruses, but the viral thymidine kinase genes were the first to be sequenced. These enzymes have been extraordinarily useful to the researcher, serving first to help label DNA, then to get thymidine analogs incorporated into DNA for therapeutic and other purposes and more recently to move genes from one genome to another. Knowledge of the nucleotide and amino acid sequences of these enzymes has allowed some deductions about their possible three-dimensional structure, as well as the location on the polypeptide of various functions; it has also allowed their classification into two main groups: the herpesviral thymidine/eukaryotic deoxycytidine kinases and the poxviral and cellular thymidine kinases; the relationships of the **mitochondrial** enzyme are still not clear.

AB **Adenylate kinase** is an ubiquitous enzyme which contributes to homeostasis of adenine nucleotide composition in the cell. In vertebrates, three isozymes (AK1, AK2, and AK3) are characterized which have distinct distribution in tissues as well as subcellular compartments. The genetic backgrounds of these **adenylate kinase** isozymes were analyzed. cDNA **clones** for AK1 were isolated from poly(A)+RNA of chicken skeletal muscle. The results of mRNA analysis in various tissues using the AK1 cDNA indicated that the AK1 gene **expression** is regulated both tissue-specifically and developmentally at the transcriptional level. The AK1 gene was **cloned** from chicken and **human** DNA and characterized. Both genes were split into seven exons. The intron positions in both genes coincided. cDNA **clones** for AK2 isolated from bovine liver poly(A)+RNA contained two types. One type (AK2A) encoded the same amino acid sequence as that reported for bovine heart AK2. The other type (AK2B) encoded the same sequence as AK2 except for the COOH terminus. The mRNA species corresponding to the two cDNA **clones** were

identified in bovine liver and heart. Both the cDNA sequences were found to direct the active **adenylate kinase** synthesis in E. coli. The AK2 gene was **cloned** and characterized. It consisted of seven exons and six introns. From genomic structure analysis, the two cDNA species were shown to be derived from a single gene by the alternative splicing mechanism. Three types of cDNA **clones** for AK3 were isolated from bovine liver poly(A)+RNA, which contained the common AK3-coding region and different 3' portions. No NH2-terminal presequence of **mitochondrial** targeting was identified in AK3 from the sequencing and **expression** analyses of the cDNA. Upon **expression** of the cDNA sequence in E. coli, AK3 protein was recovered in the periplasmic space of the bacteria, indicating that AK3 without presequence was exported through the inner bacterial membrane as it is imported through the **mitochondrial** membranes. Internal targeting signals may be responsible for the translocation process. The AK3 gene was **cloned** and partially characterized. It is split into at least five exons. The comparisons of amino acid sequences and genomic structure of three isozymes revealed that a segment corresponding to either exon 5 of the AK2 gene or a part of exon 3 of the AK3 gene is missing in the AK1 gene. Phylogenetic analysis suggested that AK1, a shorter molecule, would have been separated from a longer molecule very early in evolution of **adenylate kinase**.(ABSTRACT TRUNCATED AT 400 WORDS)

AB Three different types of cDNA **clones** for **mitochondrial** GTP:AMP phosphotransferase (AK3) were isolated from a cDNA library of bovine liver poly(A)+ RNA. Nucleotide sequencing revealed that each of these **clones** consisted of a common 5'-untranslated region, a common AK3-coding sequence and a 3'-untranslated region with different sizes. By Northern blot analysis, three species of AK3 mRNA apparently corresponding to the isolated cDNA **clones** were detected, which would be a result of varying terminations and polyadenylations of the primary transcript. From comparison of the size of the product synthesized in vitro from the message directed by the isolated cDNA with that of the purified AK3 protein, AK3 appeared to have no cleavable NH2-terminal sequence as found in other **mitochondrial** proteins. The AK3 cDNA was **expressed** in Escherichia coli, which resulted in complementation of an **adenylate kinase** mutation of E. coli. The AK3 product was exported to the periplasmic space through the bacterial inner membrane. The possible involvement of the NH2-terminal sequence of the protein in targeting to the

mitochondrial matrix was discussed.

AB **Adenylate kinase** has been purified approximately 1360-fold to a final specific activity of 280 .mu.mol of ATP formed min-1xmg-1 of protein at 30.degree.C from normal **human** liver **mitochondria**. The purity of the final preparation was evaluated by studies with polyacrylamide gel electrophoresis and sodium dodecyl sulfate-polyacrylamide gel electrophoresis and by sedimentation studies. The purified enzyme catalyzes transphosphorylation reactions between adenosine triphosphate (ATP) and adenosine monophosphate (AMP). ATP and adenosine-5'-thiophosphate, ATP and adenosine monophosphate-3'-pyrophosphate, adenosine-s'-(3-thio)triphosphate and AMP. The nearly constant ratios of these activities throughout the purification scheme suggest that all are catalyzed by the same enzyme. The purified enzyme has a molecular weight of 25,200 by sedimentation equilibrium with the use of a partial specific volume of 0.73 mlxg-1 calculated from amino acid analysis. This purified enzyme was also found to be a single polypeptide with a molecular weight of 26,500 by sodium dodecyl sulfate-polyacrylamide gel electrophoresis. From amino acid analysis, a calculated minimum molecular weight of 26,349 was obtained. Initial velocity studies revealed a narrow specificity for adenine nucleotides. The Kd' values for MgATP2- and MgATP2-.gamma.S1 were 0.12 and 0.57 .mu.M with Vmax.forward values of 1.04 (.+-.0.04)x103 and 7.02x102 .mu.mol x min-1 x mg-1, respectively. For the monophosphate acceptor, Kd' values of 0.56 and 186 .mu.M were measured for 5'-AMP2- and AMP2-.alpha.S, respectively. The Kd' for MgADP1- and ADP3- were 0.53 and 0.17 .mu.M with a Vmax.reverse of 6.40(.+-.0.03)x102 .mu.molxmin-1xmg-1 of protein. The steady state kinetics, at pH 7.4, 30.degree.C, and essentially fixed .DELTA./2 of 0.16-0.18, of this enzyme seem to be adequately **expressed** by a random quasi-equilibrium type of mechanism with a rate-limiting step largely at the interconversion of the ternary complexes, as shown in rabbit muscle, calf muscle, and calf liver **adenylate kinase**. It would appear that normal **human** liver **mitochondrial adenylate kinase** largely favors the forward reaction (ADP formation). A specific anti-liver enzyme antibody obtained from rabbit serum inhibited the purified liver **mitochondrial** enzyme activity, but not the purified **human** muscle enzyme, nor the aberrant **adenylate kinase** from Duchenne dystrophic serum.

AB Chinese hamster X **human** and mouse X **human** somatic cell hybrid lines were obtained using circulating leucocytes from six chronic myeloid leukemia patients. All six patients carried the Ph1 translocation, t(9q+;22q-), characteristic of chronic myeloid leukemia, in their dividing immature granulocytes. Analysis of independent hybrid **clones** yielded the following results: 1. The chromosome 9 markers, soluble aconitase and **adenylate kinase**-1, segregated with the 9q+ derivative. The latter marker has previously been localized to 9q34. 2. The chromosome 22 markers, **mitochondrial** aconitase, N-acetyl-alpha-D-galactosaminidase, and arylsulfatase-A, also segregated with the 9q+ derivative. **Mitochondrial** aconitase has recently been assigned to 22q11 leads to 22q13. No evidence was obtained either for reciprocity of the translocation or for variations in breakpoints in different patients. The results reported in this paper provisionally assign the gene for **mitochondrial** aconitase to a region distal to the breakpoint in 22q11.

AB The tissue contents of the reactants of the myokinase (EC 2.7.4.3) and the combined glyceraldehyde-3-phophate dehydrogenase (EC 1.1.1.29)-3-phosphoglycerate kinase (EC 2.7.2.3) reactions were measured in rapidly inactivated samples of **human** blood and rat brain, muscle, and liver. The tissue contents of the reactants of the creatine kinase (EC 2.7.3.2) reaction were measured in rat brain and muscle. In vitro the value of the **expression**: KG+G = [sigma3PG] . [sigmaATP] . [sigmalactate] KLDH = [sigmaHAP]/22] . [sigmaADP][sigmaPi] . [sigmaRUVATE] (1) was found to be 0.725 x 10(7) M-1 at I = 0.25, T = 38 degrees C, and free [Mg2+] = 0.15 mM and the value measured in vivo in red cell was 0.699 x 10(7) M-1. The value of the **expression** KMYK = ([sigma ATP] [sigma AMP]/[ADP2]) measured under the above conditions and at pH 7.2 was found to be 0.744 while the value found in red cell was 0.784 +/- 0.037. These reactions, therefore, appear to be in a state of near-equilibrium in the red cell and the measured tissue contents of ATP and ADP, which are common reactants in both reactions, approximate closely the activity of these reactants in vivo. In brain and muscle, the value of KG + G/KLDH calculated from the measured tissue contents of the reactants was a factor of 20 or more lower than that expected at equilibrium as was the measured value of the **expression**: KCK = [sigma ATP] [sigma creatine] divided by [sigma ADP] [sigma creatine-P] [H+] (2) Substitution of calculated free [sigma ADP] values in the **expression** of KG + G/KLDH gave values of 0.83 +/- 0.19 x 10(7) M-1 for brain and muscle, respectively, which agreed well with the value of 1.65 x 10(7) M-1 measured in vitro at I = 0.25, free [Mg2+] = 1 mM, T = 38 degrees C. This agreement between two highly active enzyme systems in the same compartment is taken as evidence of the existence of near-equilibrium in both these systems and suggests that free cytosolic [sigma ADP] is probably 20-fold lower than measured cell ADP content in **mitochondrial**-containing tissues.

AB Androgen is involved in both normal development and malignant transformation of prostate cells. The signal transduction pathways associated with these processes are not well understood. Using a novel kinase display approach, we have identified a protein kinase, human male germ cell-associated kinase (**hMAK**), which is transcriptionally

induced by the androgenic hormone 5alpha-dihydrotestosterone (DHT). The kinetics of induction is rapid and dose-dependent, and the induction is not blocked by cycloheximide treatment. Real time reverse transcription-PCR studies demonstrated a 9-fold induction of **hMAK** by 10 nm DHT at 24 h post-stimulation. The expression levels of **hMAK** in prostate cancer cell lines are in general higher than those of normal prostate epithelial cells. A reverse transcription-PCR product encompassing the entire **hMAK** open reading frame was isolated. The results from sequencing analysis showed that the **hMAK** protein is 623 amino acids in length and contains a kinase catalytic domain at its N terminus, followed by a proline/glutamine-rich domain. The catalytic domain of this kinase contains sequence motifs related to both the cyclin-dependent kinase and the mitogen-activated protein kinase families. When expressed in COS1 cells, **hMAK** is kinase-active as demonstrated by autophosphorylation and phosphorylation of exogenous substrate and is localized in the nucleus. A 3.7-kilobase pair promoter of the **hMAK** locus was isolated from a human genomic DNA bacterial artificial chromosome clone and was shown to be activated by DHT. This activation can be blocked by an anti-androgen drug bicalutamide (Casodex), implicating the involvement of androgen receptor in this process. Taken together, these data suggest that **hMAK** is a protein kinase targeted by androgen that may participate in androgen-mediated signaling in prostate cancer cells.

AB A purified mitochondrial adenylate-kinase (EC-2.7.4.3) with a given protein sequence is claimed. Also claimed is a nucleic acid encoding the kinase, of given nucleotide sequence, and that hybridizes, under

stringent conditions, with the given nucleic acid sequence. The claims also cover a nucleic acid complementary to the given sequence, and a DNA probe that constitutes part of that complementary sequence. Also covered are an expression vector containing the given nucleic acid sequence, a host cell transformed by that vector, and a means of preparing the adenylate-kinase by culturing the transformed cell, and recovering the protein. The claims extend to a composition containing the adenylate-kinase, and an antibody, agonist and antagonist of the protein. These are used to treat neurological disorders, cancer and immunological disorders. Also claimed is a means of detecting nucleic acids encoding mitochondrial adenylate-kinase in a sample using the DNA probe, and detecting the hybridization complex. The nucleic acids can also be administered for gene therapy. (63pp)

L13   ANSWER 1 OF 1  BIOTECHDS COPYRIGHT 2003 THOMSON DERWENT AND ISI
ACCESSION NUMBER: 1999-00127  BIOTECHDS
TITLE:            Human mitochondrial adenylate-
                  kinase, HMAK;
                     sense, antisense sequence, antibody, agonist and
                     antagonist used for cancer, neurological and immunological
                     disorder diagnosis and therapy
AUTHOR:           Hillman J L; Shah P

OTHER SOURCE:     WPI: 1998-557119 [47]
AB    A purified mitochondrial adenylate-kinase
      (EC-2.7.4.3) with a given protein sequence is claimed. Also claimed is a
      nucleic acid encoding the kinase, of given nucleotide sequence, and that
      hybridizes, under stringent conditions, with the given nucleic acid
      sequence. The claims also cover a nucleic acid complementary to the
      given sequence, and a DNA probe that constitutes part of that
      complementary sequence. Also covered are an expression vector containing
      the given nucleic acid sequence, a host cell transformed by that vector,
      and a means of preparing the adenylate-kinase by
      culturing the transformed cell, and recovering the protein. The claims
      extend to a composition containing the adenylate-kinase
      , and an antibody, agonist and antagonist of the protein. These are used
      to treat neurological disorders, cancer and immunological disorders.
      Also claimed is a means of detecting nucleic acids encoding
      mitochondrial adenylate-kinase in a sample
      using the DNA probe, and detecting the hybridization complex. The
      nucleic acids can also be administered for gene therapy. (63pp)
